Steps	Questions
Steps to Determine RDF Type: Step 1: Retrieve RDF Data for the URI You can query the RDF data of the URI you're working with by performing a SPARQL query, dereferencing it, or checking in a Linked Data browser. use a query like: <code>SELECT ?type WHERE { <your-uri> rdf:type ?type . }</code> This will return the RDF types of your URI. Step 2: Compare RDF Types with like <code>gn:Feature</code> If the result contains the type <code>http://www.geonames.org/ontology#GeonamesFeature</code>, it confirms that the entity is a GeoNames feature. If the type isn't a direct match but could be a subclass or similar, you may need to look for equivalence in ontologies or schema mappings.	1, Some sources, like ORCID, do not provide RDF documents. 2, Some RDF/XML documents use terms like <code>foaf:Person</code> without providing explicit URIs of <code>rdf</code> type. 3, The <code>rdf:type</code> retrieved is a subclass of an approved entity type, not an exact match
